NOVELTY - An assay for homocysteine involves contacting a biological fluid sample (1) with a reducing agent (2) and subsequently with homocysteine desulfurase (3). The sample is contacted with an agent (4) which binds, oxidizes or depotentiates (2) after being contacted with (3).

DETAILED DESCRIPTION - An INDEPENDENT CLAIM is also included for a kit for a homocysteine assay comprising

(1) homocysteine desulfurase (3) preferably (i) in lyophilized form; the lyophilisate being substantially free of thiol-containing cryo/lyoprotectants or (ii) in aqueous liquid form further containing a dithiol reducing agent (e.g. DTT (dithiothreitol), DTE (dithioerythrol), or TCEP (triscarboxyethylphosphine)) and a proteinaceous or non-proteinaceous stabilizer);

(2) a homocyst(e)ine standard (preferably several standards containing homocysteine (Hcy) or homocystine at several concentrations);

(3) reducing agent (2) (e.g. DTT, dithioerythiol, TCEP or methyl iodide); and

(4) an agent (4) which binds, oxidizes or depotentiates (2) e.g. an organic disulfide or a dithiol binding agent (preferably maleimide);

optionally at least one further reagent capable of converting the homocysteine conversion product of (3) into a detectable analyte; preferably a pyruvate deactivating agent e.g. hydrazine, acetoacetate decarboxylase, pyruvate carboxylase, hydrogen peroxide or pyruvate dehydrogenase; optionally a filter for removing pyruvate i.e. a molecular sieve; or capable of removing red blood cells from blood.

USE - For determining homocysteine levels in patients correlated to

risk of cardiovascular disease e.g. coronary heart disease, coronary artery disease, cerebrovascular disease, or peripherial vascular disorders.

Human blood was collected into vacutainer tubes containing citrate. Plasma was separated from the cells upon centrifugation at 1000 g for 10 minutes at 2 - 8 deg. C. Sample (10 micro l) was mixed with 0.47% hydrogen peroxide (10 micro l) and incubated at room temperature for 3 minutes. Enzyme reagent 1 (containing homocysteine desulfurase (0.02 U/ml), lactate dehydrogenase (20.8 micro g/ml), nicotinamide adenine dinucleotide (NADH) (50 micro M), cryo/lyoprotectant (trehalose, gelatine, maltose, dextran, mannitol, tween 20 or caseine) (0.8 wt,%), phosphate buffer (pH 8) (0.1 M), catalase (300 U/ml)) (25 micro l) was added and incubated for 30 minutes at 37 deg. C. 10 micro l of the same sample was mixed with 0.47% hydrogen peroxide and incubated at room temperature for 3 minutes. Blank reagent 1 was added and incubated for 30 minutes at 37 deg. C. Following this incubation reagent 2 was added to each and after mixing they were incubated for further 3 minutes at room temperature. Reagent 2 contained the DTT (dithiothreitol) binding agent and the acid destroyed the excess NADH. A reagent 3 was added and incubated at 37 deg. C for 15 minutes. The reaction was stopped by the addition of 6M HCl (15 micro l) and the sample was read at 550 nm. The reading obtained for the sample treated with blank reagent 1 was subtracted from the reading for the sample treated with enzyme reagent 1. The pretreatment of samples with hydrogen peroxide and the absence of catalase in reagent 1 for one set of samples were used as control.

The samples were assayed in the presence and absence of H2O2/catalase. The reduction in background had improved the precision of the assay by decreasing the % CV (coefficient or variance). The results demonstrated that the background was reduced when samples were assayed in the presence of hydrogen peroxide and catalase.

ADVANTAGE - The assay reduces the background levels, i.e. the signal generated by performance of the assay in the absence of the homocysteine conversion enzyme. The improved assay determines the homocysteine levels in patients.

AB A method for assaying SAM and SAH in a sample, said method comprising the steps of contacting a first aliquot of the sample with a ligand capable of binding to both SAM and to SAH, removing or degrading either SAM or SAH in a second aliquot of said sample, contacting said second aliquot with said ligand, and assessing the concns. of SAM and/or SAH in said first and second aliquots. A kit for use in the above method is also disclosed. The ratio of SAH to SAM is regarded as a marker for cardiovascular risk.

AB The present invention provides an improved method of assessing/quantifying the amount of homocysteine in a body fluid sample via an enzymic assay which comprises reducing background signal by treatment with one of the following: a reducing agent, a pyruvate deactivating agent, heat

treatment, or by lyophilizing or immobilizing the homocysteine converting enzyme.

AB A new, rapid, and sensitive enzymic colorimetric assay for total cysteine (tCYS) in plasma samples was developed. In addition, enzymic assay methods for total homocysteine and vitamin B6 in plasma were also developed. The simultaneous assay of tHCY, vitamin B6, and tCYS may be relevant to the study for the occurrence and prevalence of cardiovascular disease. The principles and protocols for these assays are presented.

AB   The invention concerns homocysteinases enzymes which have
     sufficient specificity for homocysteine, as compared to cysteine that
     hydrogen sulfide can be used as a measure of homocysteine in a biol. fluid
     even in the presence of substantial amts. of cysteine, exceeding the level
     of homocysteine.  The enzyme of desired specificity can be readily prepared
     by mutation and screening of naturally occurring homocysteinases
     or by constructing chimeric forms.

AB Enzymic methods to determine the concentration of pyridoxal 5'-phosphate (PLP) in biol. fluids are described. The methods of the invention are useful to assess risk for cardiovascular disease. The assay can be a homogeneous assay using the ability of PLP to function as a co-enzyme for **homocysteinase** and related enzymes and measuring the products of the reaction preferably spectrophotometrically. The invention also

includes improvements in sensitivity of assays for measuring hydrogen sulfide production by measuring fluorescence as opposed to absorbance of the oxidized product of H2S with N,N-dialkyl p-phenylene diamine.

AB Compns. and methods for assaying analytes, preferably, small mol. analytes are provided. Assay methods employ, in place of antibodies or mols. that bind to target analytes or substrates, modified enzymes, called substrate trapping enzymes. These modified enzymes retain binding affinity or have enhanced binding affinity for a target substrate or analyte, but have

attenuated catalytic activity with respect to that substrate or analyte. The modified enzymes are provided. In particular, mutant S-adenosylhomocysteine (SAH) hydrolases, substantially retaining binding affinity or having enhanced binding affinity for homocysteine or S-adenosylhomocysteine but having attenuated catalytic activity, are provided. Conjugates of the modified enzymes and a facilitating agent, such as agents that aid in purification or linkage to a solid support are also provided.

AB A method to assess the level of folate in a biol. sample comprises: providing said sample with glycine N-methyltransferase (GMT) and with an excess of S-adenosyl methionine (SAM) and of glycine; providing a control which contains no folate with said GMT and excess SAM and glycine in comparable amts. to those provided to the sample; and comparing the concentration of at least one product formed in the sample with the concns. of said product formed in the control, whereby the difference in levels of said product in the sample as compared to the control is directly proportional to the level of folate in the sample. Also disclosed is a method to detect and measure the concentration of analytes which can be subjected to protocols that generate hydrogen peroxide. This method comprises measuring the level of hydrogen peroxide by adding peroxidase and a dialkylphenylene diamine.

AB Enzymic methods to determine the concentration of pyridoxal 5'-phosphate (PLP) in biol. fluids are described. The methods of the invention are useful to assess risk for cardiovascular disease. The assay can be a homogeneous assay using the ability of PLP to function as a co-enzyme for **homocysteinase** and related enzymes and measuring the products of the reaction preferably spectrophotometrically. The invention also includes improvements in sensitivity of assays for measuring hydrogen sulfide production by measuring fluorescence as opposed to absorbance of the oxidized product of H2S with N,N-dialkyl p-phenylene diamine.

AB   Novel enzymic methods to determine the concentration of homocysteine in biol. fluids
     are described. In a typical embodiment of the invention, the biol. fluid
     sample is from a patient, and the methods of the invention are useful to
     assess risk for cardiovascular disease. The novel methods of the
     invention involve use of particular homocysteinase enzymes that
     permit the determination of homocysteine concns. in biol. samples without
     interference from the concns. of cysteine and/or of methionine that are
     routinely present in such samples. There is also provided a diagnostic
     kit for use in determining the amount of homocysteine in a biol. sample comprising
     (a) a homocysteinase having the aforementioned characteristics,
     and (b) at least one reagent capable of being used to determine the amount of
     product formed in the homocysteinase reaction. In a further
     aspect, the homocysteinase is provided as a chimeric mol. that
     comprises amino acid subsequences derived from, or patterned on, more than
     one homocysteinase, and which is typically produced from a
     chimeric polynucleotide that encodes therefor. Addnl. enhancements in
     homocysteine assay methodol. include use of the enzyme
     γ-glutamylcysteine synthetase to further limit any interference from
     cysteine present in the biol. samples.

AB Novel enzymic methods to determine the concentration of homocysteine in biol. fluids are described. In a typical embodiment of the invention, the biol. fluid sample is from a patient, and the methods of the invention are useful to assess risk for cardiovascular disease. The novel methods of the invention involve use of particular **homocysteinase** enzymes that permit the determination of homocysteine concns. in biol. samples without interference from the concns. of cysteine and/or of methionine that are routinely present in such samples. There is also provided a diagnostic kit for use in determining the amount of homocysteine in a biol. sample comprising (a) a **homocysteinase** having the aforementioned characteristics, and (b) at least one reagent capable of being used to determine the amount of product formed in the **homocysteinase** reaction. In a further aspect, the **homocysteinase** is provided as a chimeric mol. that comprises amino acid subsequences derived from, or patterned on, more than one **homocysteinase**, and which is typically produced from a chimeric polynucleotide that encodes therefor. Addnl. enhancements in homocysteine assay methodol. include use of the enzyme γ-glutamylcysteine synthetase to further limit any interference from cysteine present in the biol. samples.

AB A method for quantitating L-homocysteine and/or L-methionine in a solution involves contacting a solution containing L-homocysteine and/or L-methionine with a reagent comprising **methionine** gamma-**lyase** and a cofactor capable of forming a Schiff base with the L-methionine and/or L-homocysteine for a time sufficient to catalyze the conversion of L-homocysteine and/or L-methionine to 2-ketobutyrate. The amount of 2-ketobutyrate formed is determined, and the amount of L-homocysteine and/or L-methionine present in the original solution can be determined based on the amount of 2-ketobutyrate formed. A composition for measuring the amount of L-homocysteine and/or L-methionine in a solution comprises **methionine** gamma-**lyase**, a cofactor capable of forming a Schiff base with the L-methionine and/or L-homocysteine and at least one 2-ketobutyrate detecting agent, but is substantially free of L-methionine, L-homocysteine, 2-ketobutyrate, pyruvate and mercury.

AB The novel methods of the invention involve use of particular **homocysteinase** enzymes that permit the determination of homocysteine concns. in biol. samples without interference from the concns. of cysteine and/or of methionine that are routinely present in such samples. There is also provided a diagnostic kit for use in determining the amount of homocysteine in a biol. sample comprising (a) a **homocysteinase** having the aforementioned characteristics, and (b) at least one reagent capable of being used to determine the amount of product formed in the **homocysteinase** reaction. In a further aspect, the **homocysteinase** is provided as a chimeric mol. that comprises amino acid subsequences derived from, or patterned on, more than one **homocysteinase**, and which is typically produced from a chimeric polynucleotide that encodes therefor. Addnl. enhancements in homocysteine assay methodol. include use of the enzyme γ-glutamylcysteine synthetase to further limit any interference from cysteine present in the biol. samples. This assay may be applied to the diagnosis of cardiovascular diseases.
